

# Computer Networks CS3611

# Link Layer-Part 2

Haiming Jin

The slides are adapted from those provided by Prof. J.F Kurose and K.W. Ross.

# Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

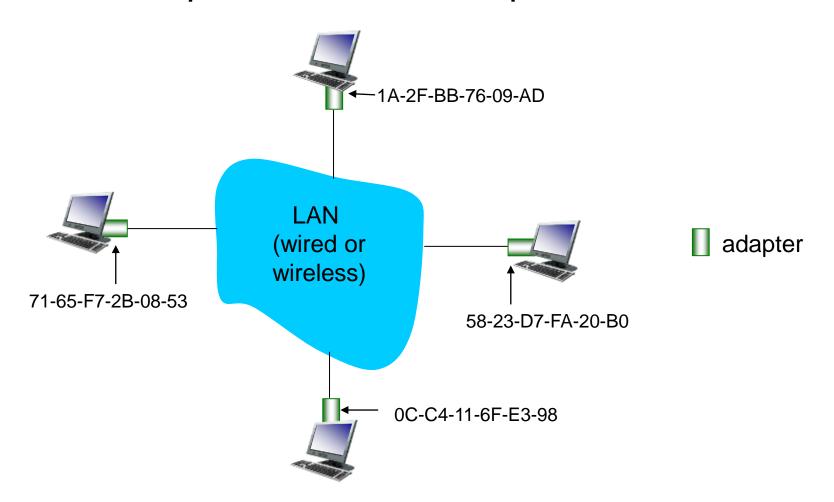

# MAC addresses and ARP

- 32-bit IP address:
  - network-layer address for interface
  - used for layer 3 (network layer) forwarding
- MAC (or LAN or physical or Ethernet) address:
  - function: used 'locally" to get frame from one interface to another physically-connected interface (same network, in IP-addressing sense)
  - 48 bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
  - e.g.: IA-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

# LAN addresses and ARP

each adapter on LAN has unique LAN address

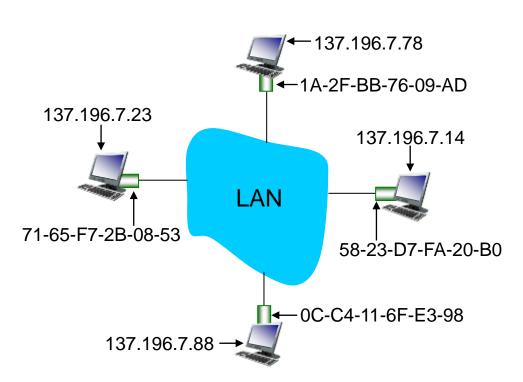

# LAN addresses (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
  - MAC address: like Social Security Number(身份证号)
  - IP address: like postal address(家庭住址)
- MAC flat address → portability
  - can move LAN card from one LAN to another
- IP hierarchical address not portable
  - address depends on IP subnet to which node is attached

# ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
  - < IP address; MAC address; TTL>
- TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

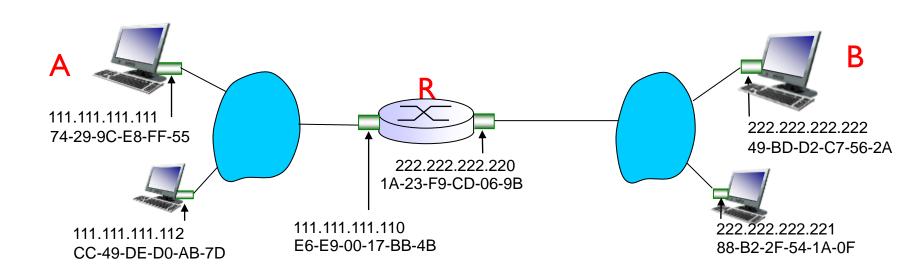

# ARP protocol: same LAN

- A wants to send datagram to B
  - B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
  - destination MAC address = FF-FF-FF-FF-FF
  - all nodes on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
  - frame sent to A's MAC address (unicast)

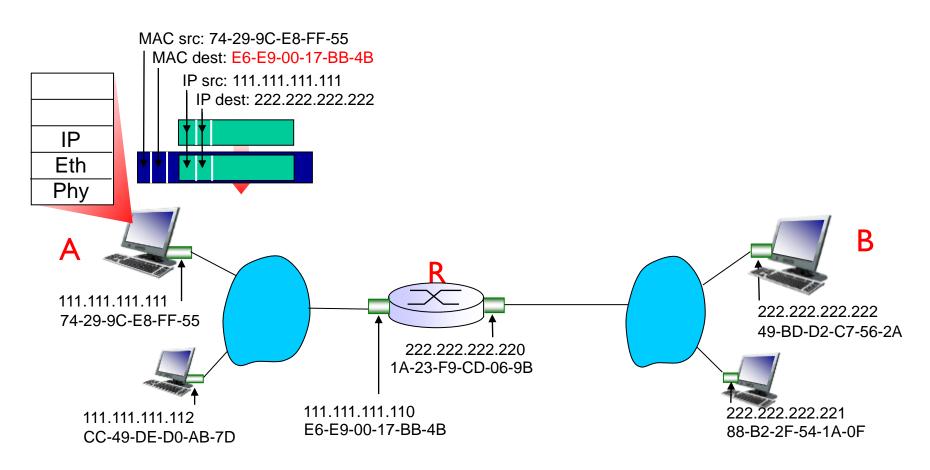

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
  - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
  - nodes create their ARP tables without intervention from net administrator

#### walkthrough: send datagram from A to B via R

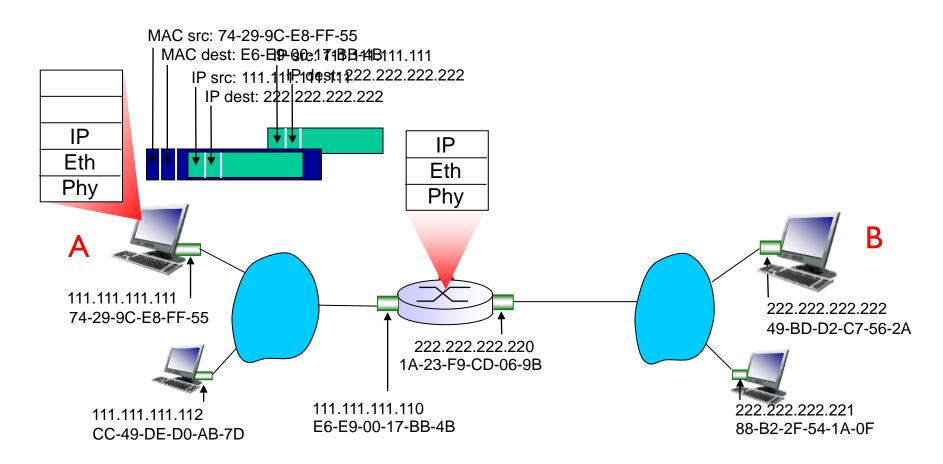

- focus on addressing at IP (datagram) and MAC layer (frame)
- assume A knows B's IP address
- assume A knows IP address of first hop router, R (how?)
- assume A knows R's MAC address (how?)

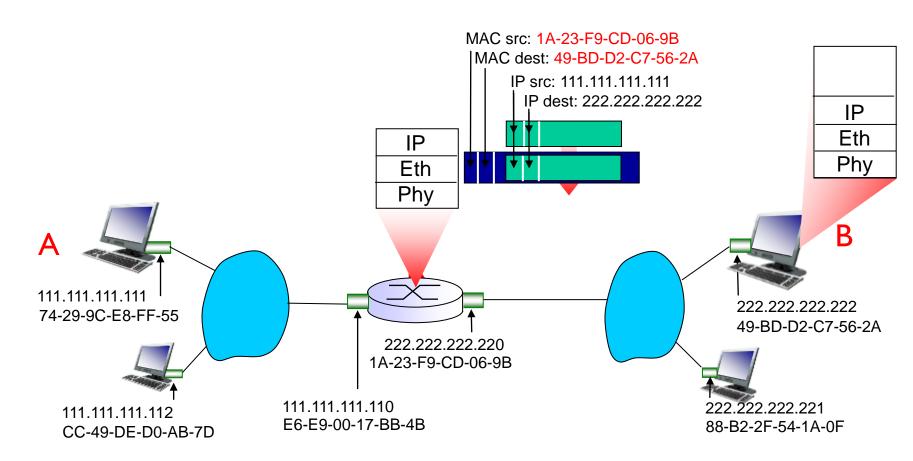

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame with R's MAC address as destination address, frame contains A-to-B IP datagram

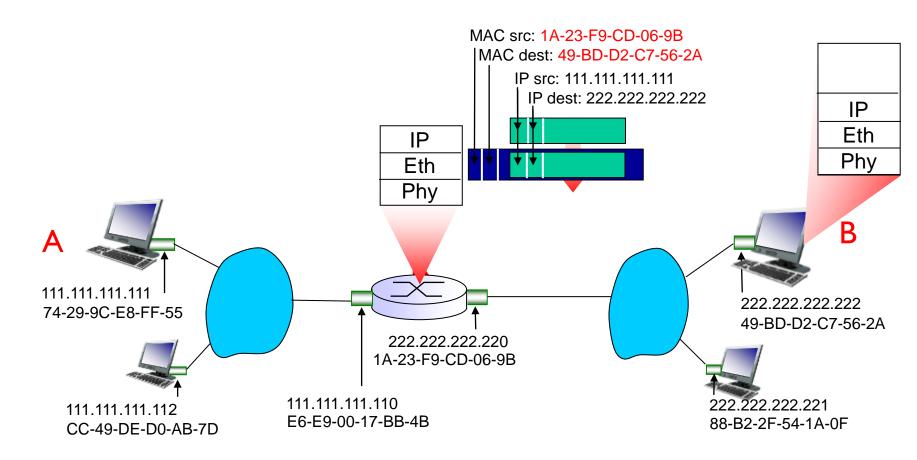

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

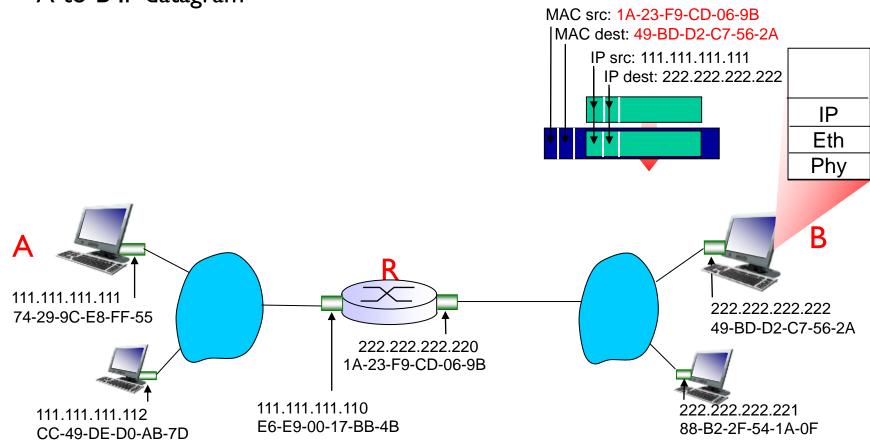

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as destination address, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as destination address, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

# Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - · addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

# Ethernet

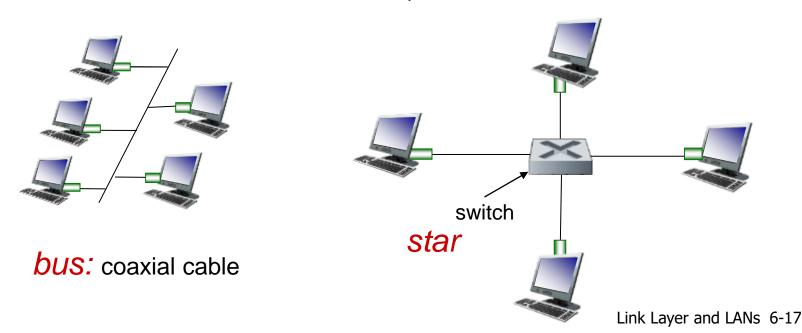

- "dominant" wired LAN technology:
- first widely used LAN technology
- simpler, cheap
- kept up with speed race: 10 Mbps 10 Gbps

Metcalfe's Ethernet sketch

# Ethernet: physical topology

- bus: popular through mid 90s
  - all nodes in same collision domain (can collide with each other)
- star: prevails today
  - active switch in center
  - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

### Ethernet frame structure

sending adapter encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame type

preamble	dest. address	source address		data (payload)	CRC
----------	------------------	-------------------	--	-------------------	-----

#### preamble:

- 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
- used to synchronize receiver, sender clock rates

# Ethernet frame structure (more)

- addresses: 6 byte source, destination MAC addresses
  - if adapter receives frame with matching destination address, or with broadcast address (e.g. ARP packet), it passes data in frame to network layer protocol
  - otherwise, adapter discards frame
- type: indicates higher layer protocol (mostly IP)
- CRC: cyclic redundancy check at receiver
  - error detected: frame is dropped

### Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- unreliable: receiving NIC doesn't send acks or nacks to sending NIC
  - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD with binary backoff

# Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

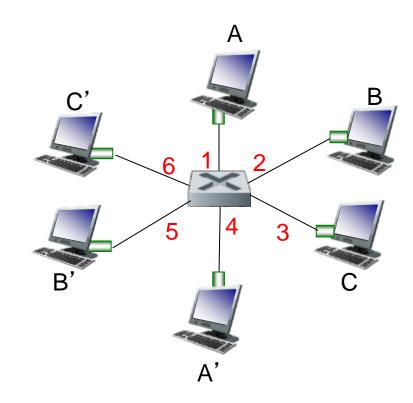

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

# Ethernet switch

- link-layer device: takes an active role
  - store, forward Ethernet frames
  - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on link, uses CSMA/CD to access link
- transparent
  - hosts are unaware of presence of switches
- plug-and-play, self-learning
  - switches do not need to be configured

#### Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, but no collisions; each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

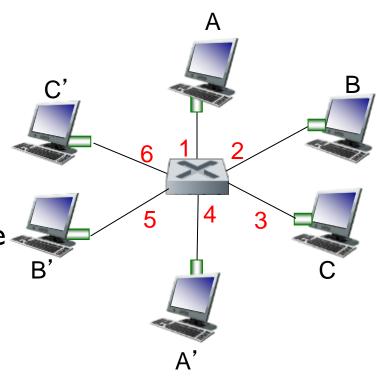

#### Switch forwarding table

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

- A: each switch has a switch table, each entry:
  - (MAC address of host, interface at to reach host, time stamp)
  - looks like a routing table!

Q: how are entries created, maintained in switch table?

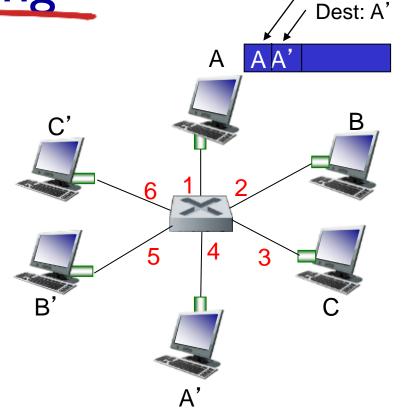

something like a routing protocol?

switch with six interfaces (1,2,3,4,5,6)

# Switch: self-learning

- switch learns which hosts can be reached through which interfaces
  - when frame received, switch "learns" location of sender: incoming LAN segment
  - records sender/location pair in switch table

MAC addr	interface	TTL
Α	1	60

Switch table (initially empty)

Source: A

# Switch: frame filtering/forwarding

#### when frame received at switch:

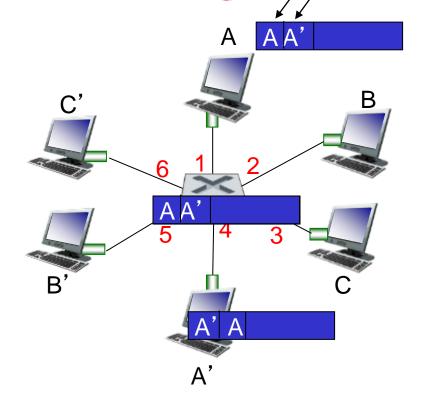

- I. record incoming link, MAC address of sending host
- 2. index switch table using MAC destination address

```
3. if entry found for destination then {
else forward frame on interface indicated by entry
}
else flood /* forward on all interfaces except arriving interface */
```

# Self-learning, forwarding: example

Source: A Dest: A'

- frame destination, A', location unknown: flood
- destination A location known: selectively send on just one link

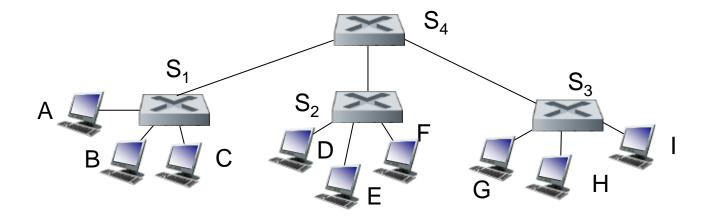

MAC addr	interface	TTL
A	1	60
Α'	4	60

switch table (initially empty)

# Interconnecting switches

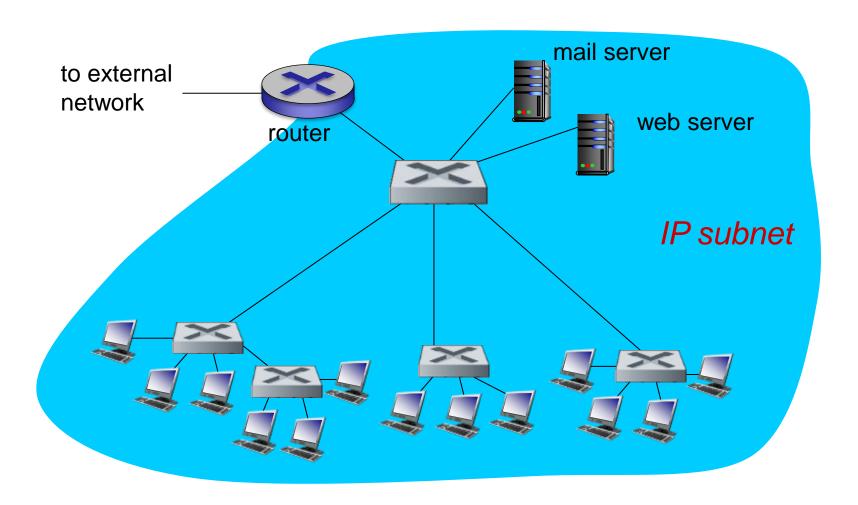

self-learning switches can be connected together:

Q: sending from A to G - how does  $S_1$  know to forward frame destined to G via  $S_4$  and  $S_3$ ?

A: self learning! (works exactly the same as in single-switch case!)

# Institutional network

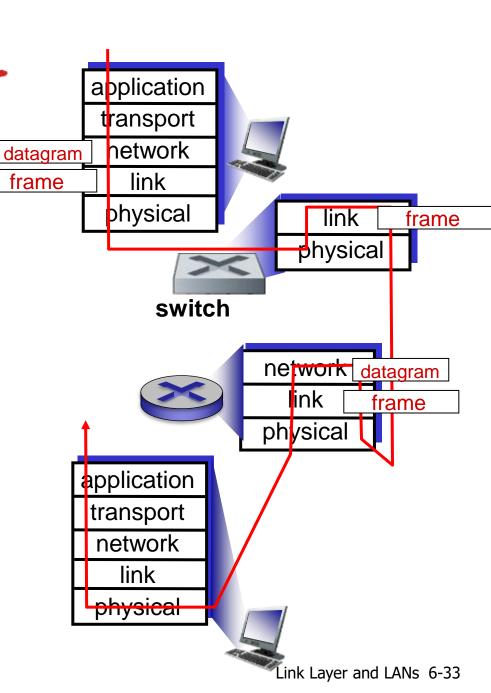

Switches vs. routers

#### both are store-and-forward:

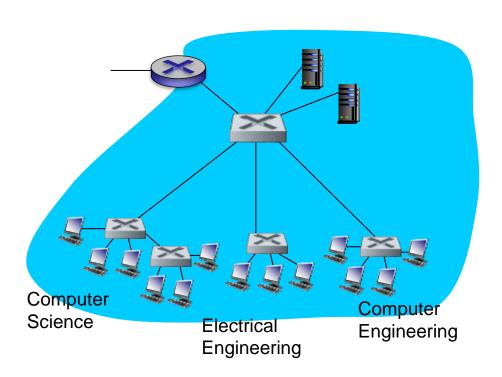

- routers: network-layer devices (examine networklayer headers)
- switches: link-layer devices (examine link-layer headers)

#### both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

# **VLANs:** motivation

#### consider:

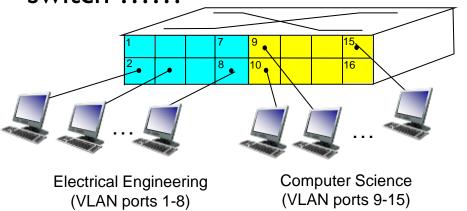

- CS user moves office to EE, but wants connect to CS switch?
- single broadcast domain:
  - all layer-2 broadcast traffic (ARP, DHCP, unknown location of destination MAC address) must cross entire LAN
  - security/privacy, efficiency issues

# **VLANs**

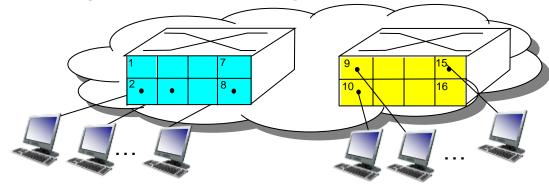

#### Virtual Local Area Network

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch .....

... operates as multiple virtual switches

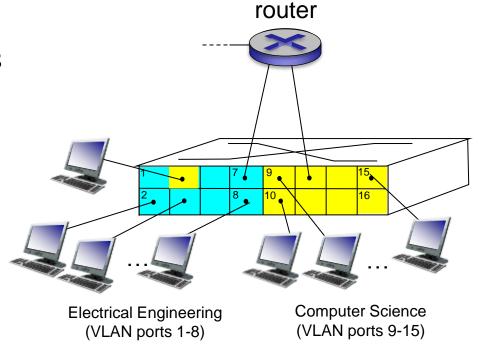

Electrical Engineering (VLAN ports 1-8)

Computer Science (VLAN ports 9-16)

# Port-based VLAN

 traffic isolation: frames to/from ports 1-8 can only reach ports 1-8

 dynamic membership: ports can be dynamically assigned among VLANs

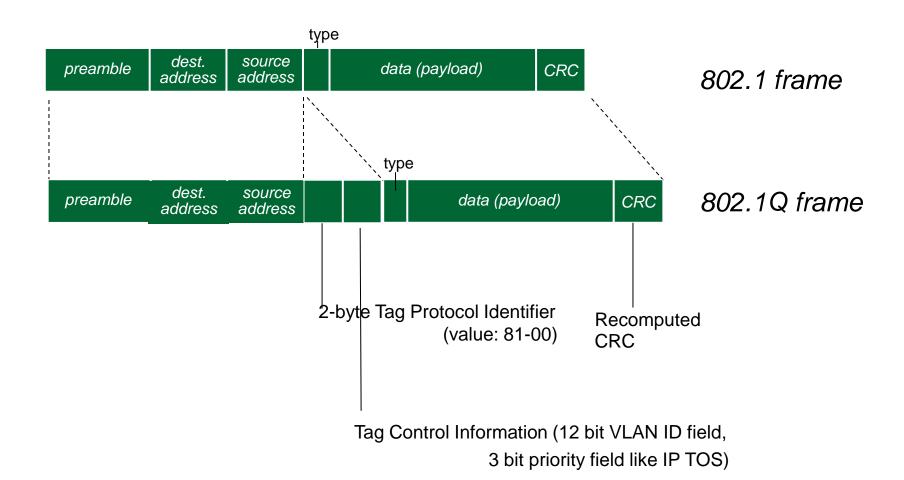

- forwarding between VLANS: done via routing (just as with separate switches)
  - in practice vendors sell combined switches plus routers

### VLANS spanning multiple switches

- trunk port: carries frames between VLANS defined over multiple physical switches
  - frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
  - 802. I q protocol adds/removed additional header fields for frames forwarded between trunk ports

### 802. I Q VLAN frame format

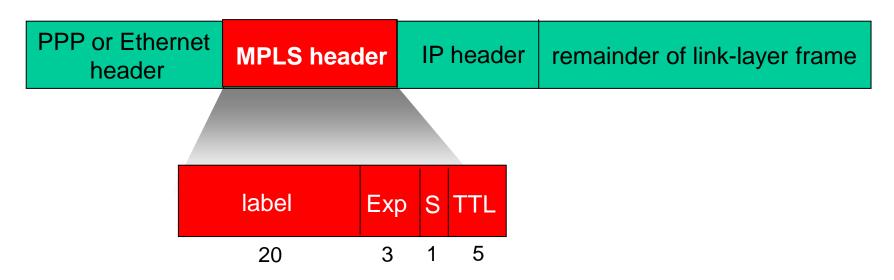

# Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

# Multiprotocol label switching (MPLS)

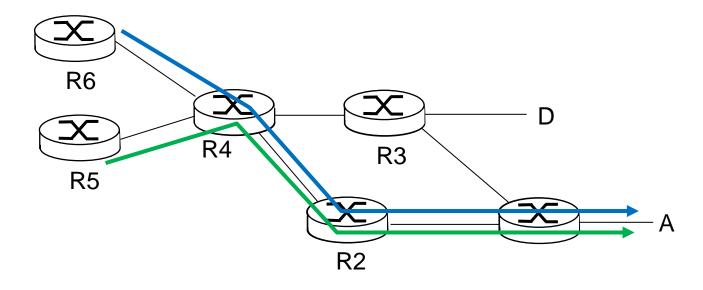

- initial goal: high-speed IP forwarding using fixed length label (instead of IP address)
  - fast lookup using fixed length identifier (rather than shortest prefix matching)
  - borrowing ideas from Virtual Circuit (VC) approach
  - but IP datagram still keeps IP address!

## MPLS capable routers

- a.k.a. label-switched router
- forward packets to outgoing interface based only on label value (don't inspect IP address)
  - MPLS forwarding table distinct from IP forwarding tables
- flexibility: MPLS forwarding decisions can differ from those of IP
  - use destination and source addresses to route flows to same destination differently (traffic engineering)
  - re-route flows quickly if link fails: pre-computed backup paths (useful for VoIP)

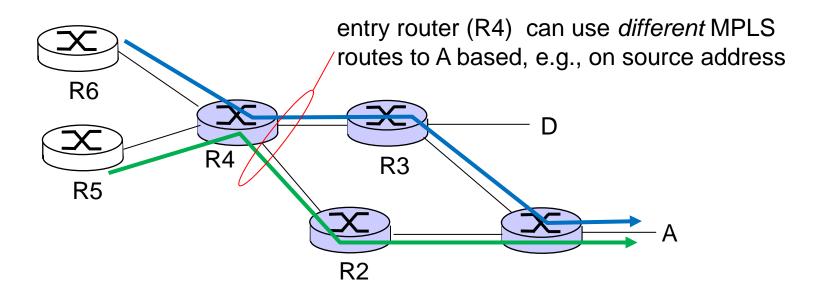

## MPLS versus IP paths

 IP routing: path to destination determined by destination address alone

### MPLS versus IP paths

 IP routing: path to destination determined by destination address alone

IP-only router

 MPLS routing: path to destination can be based on source and destination address

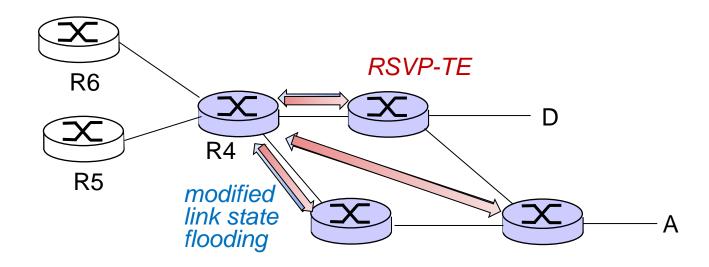

MPLS and IP router

 fast reroute: precompute backup routes in case of link failure

## MPLS signaling

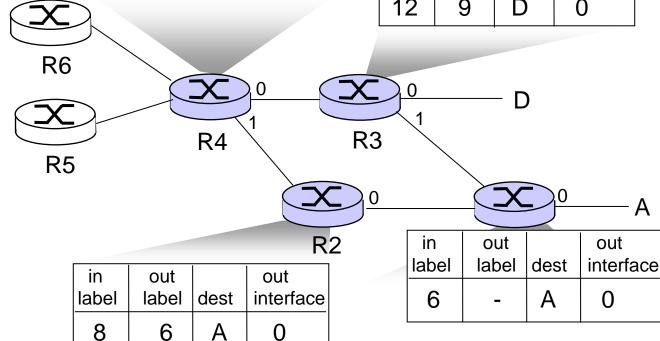

- modify OSPF, IS-IS link-state flooding protocols to carry info used by MPLS routing,
  - e.g., link bandwidth, amount of "reserved" link bandwidth
- entry MPLS router uses RSVP-TE signaling protocol to set up MPLS forwarding at downstream routers

### MPLS forwarding tables

in label	out label	dest	out interface
10	6	Α	1
12	9	D	0

## Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

### Data center networks

- 10's to 100's of thousands of hosts, often closely coupled, in close proximity:
  - e-business (e.g. Amazon)
  - content-servers (e.g., YouTube, Akamai, Apple, Microsoft)
  - search engines, data mining (e.g., Google)

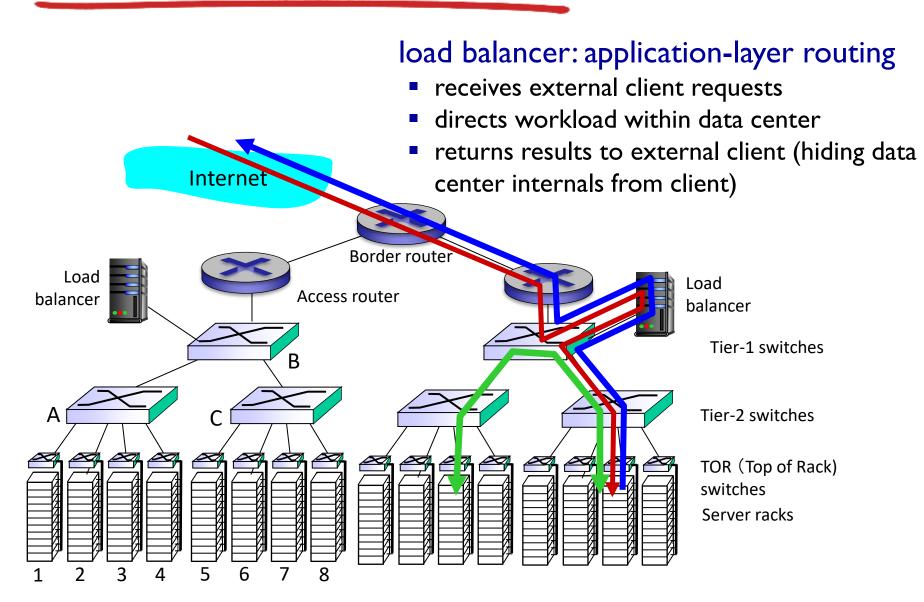

#### challenges:

- multiple applications, each serving massive numbers of clients
- managing/balancing load, avoiding processing, networking, data bottlenecks

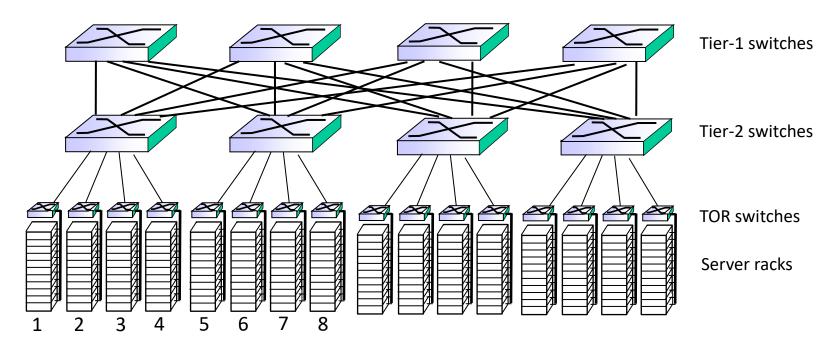

Inside a 40-ft Microsoft container, Chicago data center

### Data center networks

### Data center networks

- rich interconnection among switches, racks:
  - increased throughput between racks (multiple routing paths possible)
  - increased reliability via redundancy

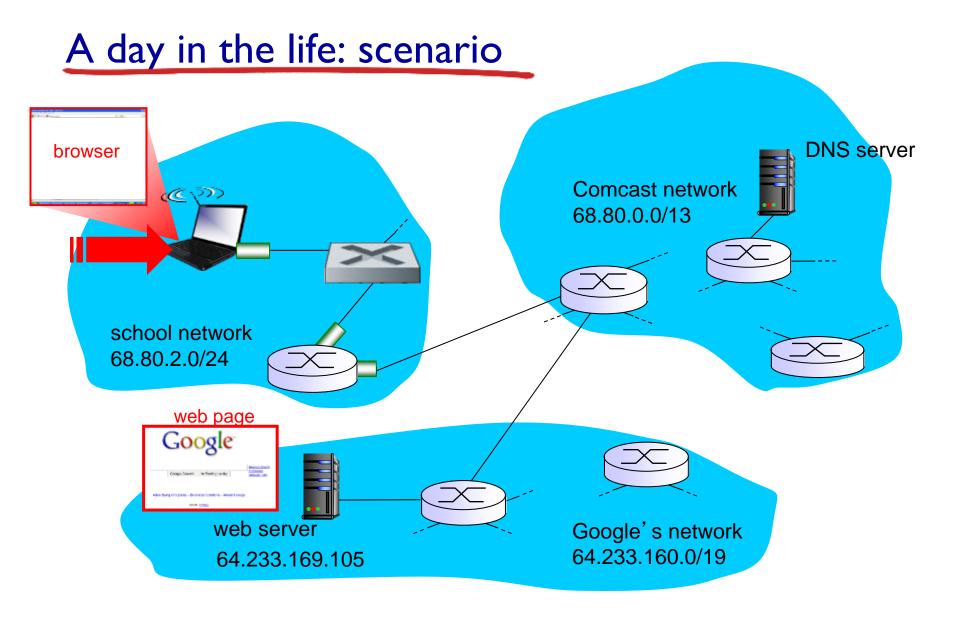

## Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 64 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

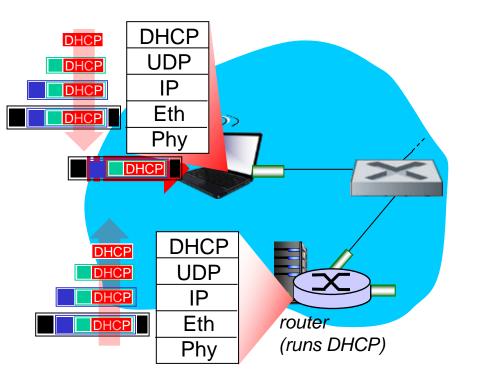

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

#### Synthesis: a day in the life of a web request

- journey down protocol stack complete!
  - application, transport, network, link
- putting-it-all-together: synthesis!
  - goal: identify, review, understand protocols (at all layers) involved in seemingly simple scenario: requesting www page
  - scenario: student attaches laptop to campus network, requests/receives www.google.com

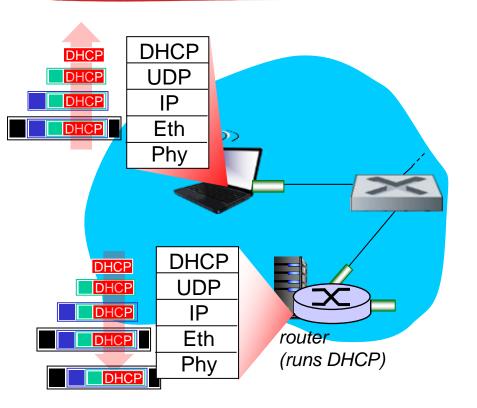

#### A day in the life... connecting to the Internet

- connecting laptop needs to get its own IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.3 Ethernet
- Ethernet frame broadcast (dest: FFFFFFFFFFFFFF) on LAN, received at router running DHCP server
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

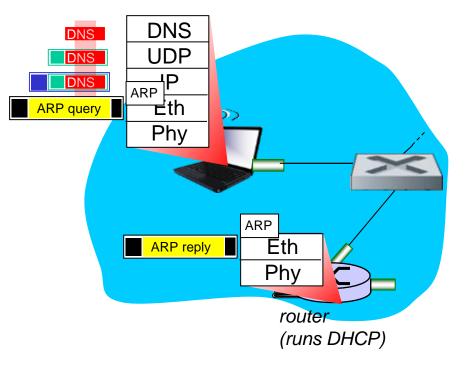

#### A day in the life... connecting to the Internet

- DHCP server formulates
   DHCP ACK containing
   client's IP address, IP
   address of first-hop router
   for client, name & IP address
   of DNS server
- encapsulation at DHCP server, frame forwarded (switch learning) through LAN, demultiplexing at client
- DHCP client receives DHCP ACK reply

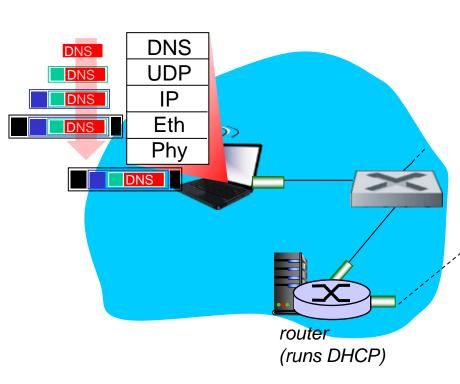

Client now has IP address, knows name & addr of DNS server, IP address of its first-hop router

#### A day in the life... ARP (before DNS, before HTTP)

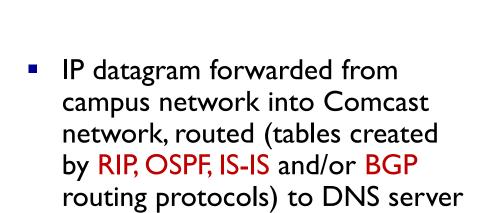

- before sending HTTP request, need IP address of www.google.com: DNS
- DNS query created, encapsulated in UDP, encapsulated in IP, encapsulated in Eth. To send frame to router, need MAC address of router interface: ARP
- ARP query broadcast, received by router, which replies with ARP reply giving MAC address of router interface
- client now knows MAC address of first hop router, so can now send frame containing DNS query

#### A day in the life... using DNS

 IP datagram containing DNS query forwarded via LAN switch from client to I<sup>st</sup> hop router

demuxed to DNS server

DNS UDP

IΡ

Eth

Phy

Comcast network

68.80.0.0/13

DNS

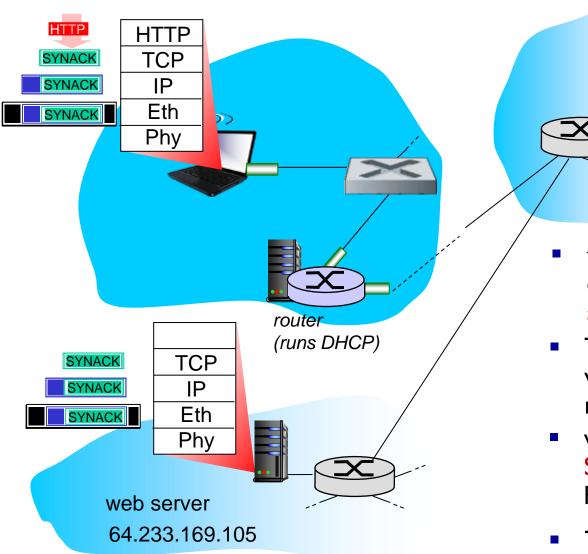

DNS

DNS

 DNS server replies to client with IP address of www.google.com

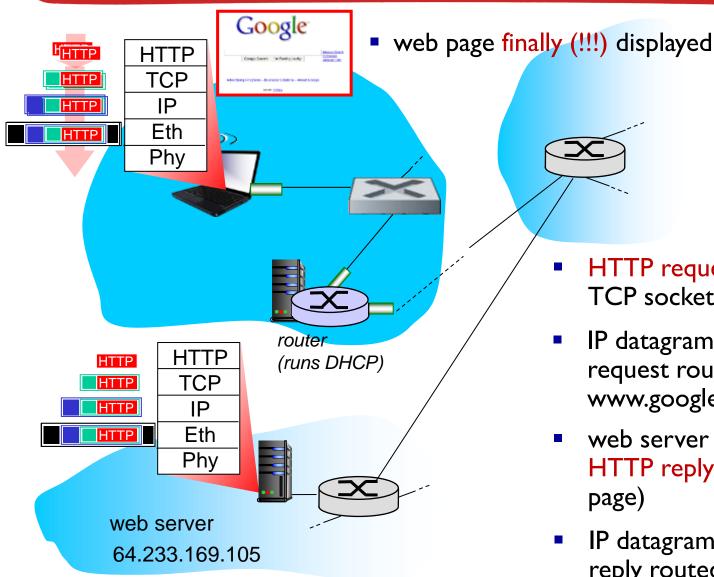

NS server

### A day in the life...TCP connection carrying HTTP

- to send HTTP request, client first opens TCP socket to web server
- TCP SYN segment (step I in 3way handshake) inter-domain routed to web server
- web server responds with TCP SYNACK (step 2 in 3-way handshake)
- TCP connection established!

### A day in the life... HTTP request/reply

- HTTP request sent into TCP socket
- IP datagram containing HTTP request routed to www.google.com
- web server responds with HTTP reply (containing web page)
- IP datagram containing HTTP reply routed back to client

## Chapter 6: Summary

- principles behind data link layer services:
  - error detection, correction
  - sharing a broadcast channel: multiple access
  - link layer addressing
- instantiation and implementation of various link layer technologies
  - Ethernet
  - switched LANS, VLANs
  - virtualized networks as a link layer: MPLS
- synthesis: a day in the life of a web request

# Chapter 6: let's take a breath

- journey down protocol stack complete (except PHY)
- solid understanding of networking principles, practice
- ..... could stop here .... but lots of interesting topics!
  - wireless
  - multimedia
  - security
